# High Performance Computing systems continue to grow in size and complexity

- The recent advent of multi- and many- core chips has only accelerated this trend
- Large scale applications require 10,000-100,000s of threads to achieve maximum performance

### Debugging technology has remained fairly constant

- Most effort is still focused on interactive debugging schemes
- It is not clear that large scale interactive debugging is compatible with the way large systems are operated

# In this talk we will look at how debugging parallel applications in an offline manner solves these issues.

Conclusions

## Large Scale Debugging

- The volume of data generated by debugging and monitoring tools requires an efficient infrastructure for collection and organization.
- Visual representation of data may be untenable for applications and systems executing at very large scales.

> {klindeku, anthony.d, dstanzi} @asu.edu

#### Challenges

- Implementation
- Interface
- Agents
- Segmentation Fault
- Deadlock
- AllgatherV
- Agent Development
- Results
- Future Work
- Conclusions

## Correctness and Performance Debugging

- Applications can be faulty without producing an error. Performance can be degraded by:
  - Calculation mistakes
  - Large amount of I/O
  - Poor communication patterns
- Inefficiency wastes expensive computational cycles
- Finding errors of this kind can be very difficult
- Future debugging systems must combine application performance and correctness data, including data across multiple runs, to find application efficiency errors.

#### Challenges

GDBase

- Implementation
- Interface
- Agents
- Segmentation Fault
- Deadlock
- AllgatherV
- Agent Development
- Results
- Future Work

Conclusions

## Reliability

- As systems grow, hardware failures occur more often
- As applications utilize more cores, hardware failures may be a part of many jobs.
- It will not be immediately clear if errors are software or hardware related
- Future debugging systems must be able to monitor system performance across jobs in order to detect hardware related errors.

> {klindeku, anthony.d, dstanzi} @asu.edu

#### Challenges

GDBase

- Implementation
- Interface
- Agents
- Segmentation Fault
- Deadlock
- AllgatherV
- Agent Development
- Results

Conclusions

## **Production Environments**

- Most sites use batch systems in order to maintain high utilization
- Interactive debugging complicates batch operation
- Sites often limit the scale at which interactive debuggers can run
- Future debugging systems must be able to operate properly inside of existing batch queuing systems so they may run at the largest scales.

Challenges

{klindeku, anthony.d, dstanzi} @asu.edu

#### Challenges

GDBase

- Implementation
- Interface
- Agents
- Segmentation Fault
- Deadlock
- AllgatherV
- Agent Development
- Results
- Future Work
- Conclusions

To summarize, future debugging systems must be able to:

- Operate within batch queue systems
- Detect hardware related errors
- Combine performance and correctness debugging information across multiple runs
- Provide different methods of presenting information
- Scale to next generation systems

> {klindeku, anthony.d, dstanzi} @asu.edu

## GDBase

In response to these challenges we have built GDBase, a framework for offline parallel debugging.

### **GDBase Provides**

- scalable offline debugging
- the functionality of GDB
- operation within batch queuing systems

### **GDBase Functionality**

- GDBase gathers runtime information from a GDB instance
- Collects this information to a distributed event database
- Provides a mechanism for analysis of this data

> {klindeku, anthony.d, dstanzi} @asu.edu

#### Challenges

#### GDBase

- Implementation
- Interface
- Agents
- Segmentation Fault
- Deadlock
- AllgatherV
- Agent Development
- Results
- Future Work
- Conclusions

## Workflow

### 1. Specify debugger behavior

 Multiple interfaces are available to users (or agents) for controlling debugger behavior

### 2. Run your application under debugger control

 Debugging messages are collected local to each task or to shared storage

### 3. Collect debugging messages

 After execution, events from debugging tasks are moved to a central location for analysis

### 4. Use analysis agents on collected information

 Agents provide a simple way for users to detect common problems

## Interface

### **Debugging Specification**

- Multiple interfaces are available: simple and advanced
- Debugging specification files allow setting of breakpoints, watchpoints and variable logging
- Aids users in the transition from interactive to offline

```
@bp functionName
variable1
variable2
@bp myapp.c:231
variable3
```

@watch myapp.c:10 variable4

```
Agent Development
```

Results

```
Future Work
```

Conclusions

## Interface

### Advanced Scripting

- If you need more control, use a debugging script
- Debugging scripts are written in TCL
- Provides fine grained control over GDB
- Intended for agent development

```
proc user_setup {} {
  gdb_setBreakpoint "main" "myMethod"
  db_logMessage "user.break" [gdb_lastOutput]
```

Messages are stored in the database as a key-value pair using the db\_logMessage command.

Conclusions

## **Deadlock Agent**

The Deadlock Agent identifies tasks involved in a communication pattern that cannot continue. The tasks are then organized according to number of dependencies. A report is produced containing:

- Outstanding communications
- Location in code for each task
- Stack for each Task

This Agent was motivated by user problems in an asynchronously communicating code. A race condition existed causing the program to randomly deadlock during execution.

Implementation

Interface

Agents

Segmentation Fault

Deadlock

AllgatherV Agent Development

Results

Future Work

Conclusions

## Deadlock Agent Usage

#### Job Exection

baseexec --agent deadlock -t 600 ./myprogram

- Deadlock catches each Send and Recv from an application and logs their parameters, start, and end to the database.
- The -t option tells the program to time out if it has not received an event from the program in x seconds.

## AllgatherV Agent

An AllgatherV collects variable amounts of data from each task and puts the resulting array on every task.

AllgatherV can also alter the order of data based on task.

The AllgatherV Agent analyzes each AllgatherV call across tasks to:

- Identify improper item counts
- Identify improper offset values

The Agent then produces a report with the affected Task, Location in Code, etc.

Results

Future Work

Conclusions

## Agent Development

- Python API for accessing database (anything that can query a SQL database will work)
- Provides an abstraction for reading messages
- Provides helper methods for parsing gdb output

```
from gdbase import *
##connect to database
db = GDBase()
db.connect()
## obtains job id to read from environment
J = db.getJob()
## Look for messages starting with 'opd.SEGFAULT'
M = J.getMessages()
M.setKey('opd.SEGFAULT')
```

Conclusions

### **User Experience**

GDBase was used to find several bugs in a user Finite Difference Time Domain (FDTD) code using the Segmentation Fault Agent and its generated report. Three bugs were found:

- Swapped loop indexes on nested loops
- Incorrect ghost row boundries on another loop
- Incorrect initialization on another loop

Each of these bugs caused the application to crash at sizes about 1024 tasks.

> {klindeku, anthony.d, dstanzi} @asu.edu

Conclusions

## Future Work

Continued development of the GDBase will focus on:

- Test scalability at 50,000 tasks
- Comprehensive user interface (web or graphical)
- Enhancing the facilities provided through the interfaces
- Developing additional analysis agents, including ones that compare data between runs
- Adding support for other tools besides GDB, such as performance and profiling tools (Tau, DPCL)

> {klindeku, anthony.d, dstanzi} @asu.edu

#### Challenges
